AI Career Compass | short design reflection

Snapshot	2026-09-21
Postings / companies	852 / 107
Source checks	198

Design decision

The product visualizes 852 public postings to support career exploration. Opportunity landscape describes where postings appear, Skill lab tests local skill mentions, and Job postings keeps every posting inspectable by experience, skills, direction, location, and source.

What the evidence supports

The filtered charts support descriptive questions about direction, experience, regions, and skill-mention coverage. All three views share role, experience, location, and graduate filters; Job postings adds posting search and a canonical skill-mention filter that can carry into the charts and Skill lab. Official source links and Project files downloads preserve provenance.

What remains uncertain

This is a non-representative ATS sample. Automated skill extraction uses a fixed vocabulary, so tracked terms are overrepresented. Unknown skill is not skill absence, experience bucket is not graduate eligibility, and mention coverage is not proficiency or readiness. Early career evidence can require experience; it is kept separate from explicit graduate evidence.

AI assistance and privacy

AI assisted extraction, normalization, and copy review; source URLs, review labels, and limitations remain visible. Skill chips are local-only and optional device memory does not send a profile to a server. No applicant data or shortlist is collected.

Target choice

We compared 40, 50, 60, 70 and 80 percent targets. Sixty percent requires a majority without the sharper sparsity at higher targets. It is a design choice, not a validated hiring cutoff. See the reproducible skill-target study.

Next iteration

Repeat collection with the same schema, add documented human adjudication for ambiguous skill mentions, and compare ranked recommendations against a written review sample. Keep the interface focused on evidence and learning prompts.
